COS 318: Operating Systems Virtual Memory Paging

Jaswinder Pal Singh Computer Science Department **Princeton University**

(http://www.cs.princeton.edu/courses/cos318/)

Today's Topics

- Paging mechanism
- Page replacement algorithms

Virtual Memory Paging

Simple world

Load entire process into memory. Run it. Exit.

Problems

- Slow (especially with big processes)
- Wasteful of space (doesn't use all of its memory all the time)

Solution

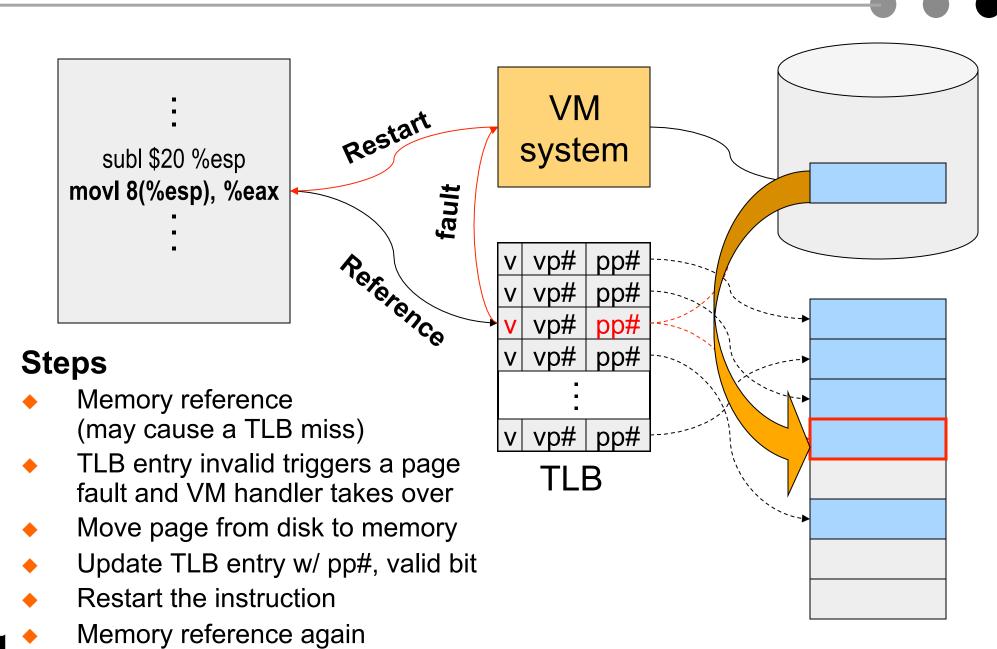

- Demand paging: only bring in pages actually used
- Paging: only keep frequently used pages in memory

Mechanism:

Virtual memory maps some to physical pages, some to disk

VM Paging Steps

Virtual Memory Issues

- How to switch a process after a fault?
 - Need to save state and resume
 - Is it the same as an interrupt?
- What to page in?
 - Just the faulting page or more?
 - Want to know the future...
- What to replace?
 - Cache (main memory) always too small, which page to replace?
 - Want to know the future...

How Does Page Fault Work?

- User program should not be aware of the page fault
- Fault may have happened in the middle of the instruction!
- Can we skip the faulting instruction?
- Is a faulting instruction always restartable?

What to Page In?

- Page in the faulting page
 - Simplest, but each "page in" has substantial overhead
- Page in more pages each time
 - May reduce page faults if the additional pages are used
 - Waste space and time if they are not used
 - Real systems do some kind of prefetching
- Applications control what to page in
 - Some systems support for user-controlled prefetching
 - But, many applications do not always know

VM Page Replacement

- Things are not always available when you want them
 - It is possible that no unused page frame is available
 - VM needs to do page replacement
- On a page fault
 - If there is an unused frame, get it
 - If no unused page frame available,
 - Choose a used page frame
 - If it has been modified, write it to disk
 - Invalidate its current PTE and TLB entry
 - Load the new page from disk
 - Update the faulting PTE and remove its TLB entry
 - Restart the faulting instruction
- General data structures
 - A list of unused page frames
 - A table to map page frames to PID and virtual pages. Why?

Page Replacement

Which "Used" Page Frame To Replace?

- Random
- Optimal or MIN algorithm
- NRU (Not Recently Used)
- FIFO (First-In-First-Out)
- FIFO with second chance
- Clock
- LRU (Least Recently Used)
- NFU (Not Frequently Used)
- Aging (approximate LRU)
- Working Set
- WSClock

Optimal or MIN

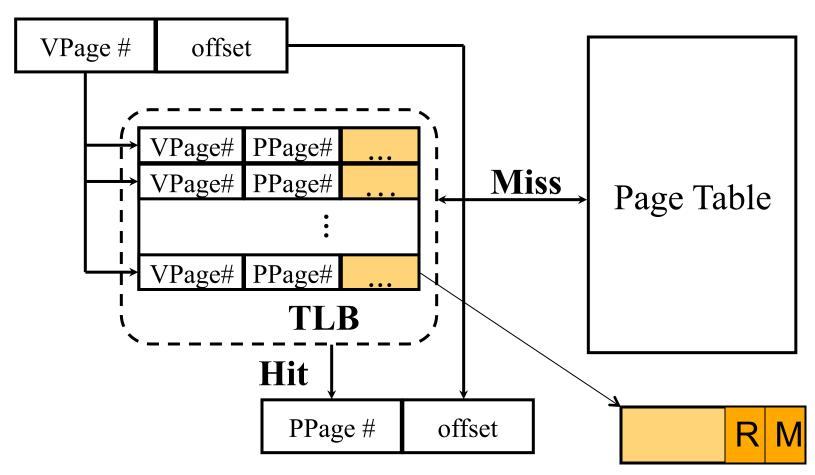

Algorithm:

- Replace the page that won't be used for the longest time (Know all references in the future)
- Example
 - Reference string: 1 2 3 4 1 2 5 1 2 3 4 5
 - 4 page frames
 - 6 faults
- Pros
 - Optimal solution and can be used as an off-line analysis method
- Cons
 - No on-line implementation

Revisit TLB and Page Table

Virtual address

- Important bits for paging
 - Reference: Set when referencing a location in the page (can clear every so often, e.g. on clock interrupt)
 - Modify: Set when writing to a location in the page

Not Recently Used (NRU)

Algorithm

- Randomly pick a page from the following (in this order)
 - Not referenced and not modified
 - Not referenced and modified
 - · Referenced and not modified
 - Referenced and modified
- Clear reference bits

Example

- 4 page frames
- Reference string
- 8 page faults

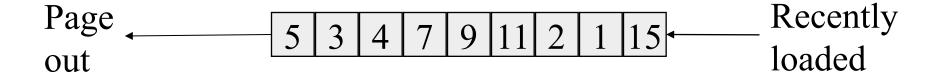

1 2 3 4 1 2 5 1 2 3 4 5

Pros

- Implementable
- Cons
 - Require scanning through reference bits and modified bits

First-In-First-Out (FIFO)

1 | 2 | 3 | 4 | 1 2 | 5 | 1 | 2 | 3 | 4 | 5 |

- Algorithm
 - Throw out the oldest page
- Example
 - 4 page frames
 - Reference string
 - 10 page faults
- Pros
 - Low-overhead implementation
- Cons
 - May replace the heavily used pages

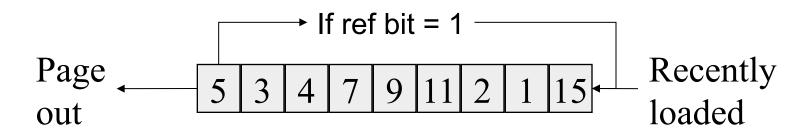

More Frames → Fewer Page Faults?

- Algorithm: FIFO replacement
- Reference string: 1 2 3 4 1 2 5 1 2 3 4 5
- 10 page faults
- Same string with 3 page frames
 - Algorithm: FIFO replacement
 - Reference string:
 - 9 page faults!
- 1 2 3 4 1 2 5 1 2 3 4 5
- This is so called "Belady's anomaly" (Belady, Nelson, Shedler 1969)

FIFO with 2nd Chance

1 2 3 4 1 2 5 1 2 3 4 5

Algorithm

- Check the reference-bit of the oldest page
- If it is 0, then replace it
- If it is 1, clear the reference bit, put the page to the end of the list, and continue searching
- Looking for an old page not referenced in current clock interval, for example

Example

- 4 page frames
- Reference string:
- 8 page faults

Pros

Simple to implement

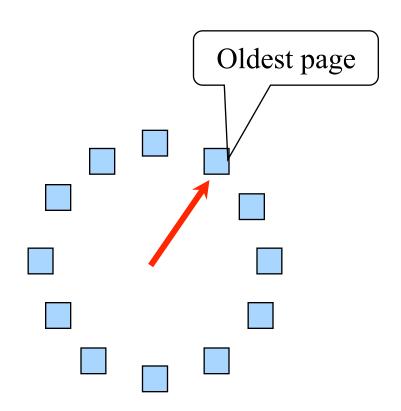

Cons

The worst case may take a long time

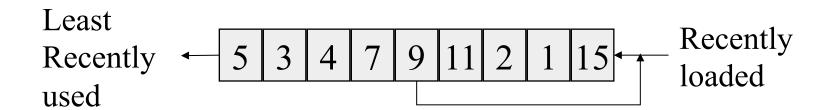

Clock

- FIFO clock algorithm
 - Hand points to the oldest page
 - On a page fault, follow the hand to inspect pages
- Second chance
 - If the reference bit is 1, set it to 0 and advance the hand
 - If the reference bit is 0, use it for replacement
- Compare with the FIFO with 2nd chance
 - What's the difference?
- What if memory is very large
 - Take a long time to go around?

Least Recently Used

Algorithm

- Replace page that hasn't been used for the longest time
 - Order the pages by time of reference
 - Timestamp for each referenced page

Example

- 4 page frames
- Reference string:
- 8 page faults

1 2 3 4 1 2 5 1 2 3 4 5

Pros

Good to approximate MIN

Cons

Difficult to implement

Approximation of LRU

- For each memory reference, store the ticks in its PTE
- Find the page with minimal ticks value to replace
- Use a smaller counter

Most recently used

Least recently used

LRU

N categories

Pages in order of last reference

Crude LRU

Pages referenced since the last page fault

Pages not referenced since the last page fault 2 categories

8-bit

count

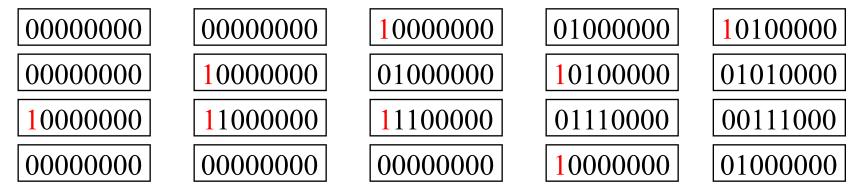

256 categories

Aging: Not Frequently Used (NFU)

- Algorithm
 - Shift reference bits into counters
 - Pick the page with the smallest counter to replace

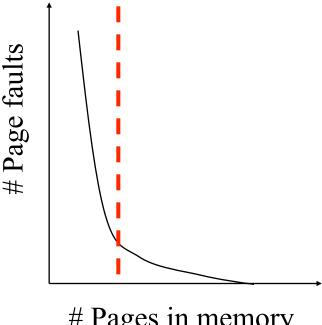

- Old example
 - 4 page frames
 - Reference string:
 8 page faults
 1 2 3 4 1 2 5 1 2 3 4 5
- Main difference between NFU and LRU?
 - NFU has a short history (counter length)
- How many bits are enough?
 - In practice 8 bits are quite good

Program Behavior (Denning 1968)

♦ 80/20 rule

- > 80% memory references are within <20% of memory space
- > 80% memory references are made by < 20% of code
- Spatial locality
 - Neighbors are likely to be accessed
- Temporal locality
 - The same page is likely to be accessed again in the near future

Pages in memory

Working Set

- Main idea (Denning 1968, 1970)
 - Define a working set as the set of pages in the most recent K page references
 - Keep the working set in memory will reduce page faults significantly
- Approximate working set
 - The set of pages of a process used in the last T seconds
- An algorithm
 - On a page fault, scan through all pages of the process
 - If the reference bit is 1, record the current time for the page
 - If the reference bit is 0, check the "time of last use,"
 - If the page has not been used within T, replace the page
 - Otherwise, go to the next
 - Add the faulting page to the working set

WSClock

- Follow the clock hand
- If the reference bit is 1
 - Set reference bit to 0
 - Set the current time for the page
 - Advance the clock hand
- If the reference bit is 0, check "time of last use"
 - If the page has been used within δ , go to the next
 - If the page has not been used within δ and modify bit is 1
 - Schedule the page for page out and go to the next
 - If the page has not been used within δ and modify bit is 0
 - Replace this page

Replacement Algorithms

The algorithms

- Random
- Optimal or MIN algorithm
- NRU (Not Recently Used)
- FIFO (First-In-First-Out)
- FIFO with second chance
- Clock
- LRU (Least Recently Used)
- NFU (Not Frequently Used)
- Aging (approximate LRU)
- Working Set
- WSClock
- Which are your top two?

Summary

- VM paging
 - Page fault handler
 - What to page in
 - What to page out
- LRU is good but difficult to implement
- Clock (FIFO with 2nd hand) is considered a good practical solution
- Working set concept is important
