## Last Time: Parallel Programming Disciplines

- Programming with shared mutable data
- Very hard! Had to remember to:
- acquire and release locks in the right places
- acquire locks in the right order
- once you are done writing your program, how do you test it?
- how do you verify you haven't made a mistake?
- With pure functional code and parallel futures, many error modes disappear
- Are there more great abstractions like futures?
- you betcha!

## What if you had a really big job to do?

- Eg: Create an index of every web page on the planet.
- Google does that regularly!
- There are billions of them!
- Eg: search facebook for a friend or twitter for a tweet
- To get big jobs done, we typically need to harness 1000s of computers at a time, but:
- how do we distribute work across all those computers?
- you definitely can't use shared memory parallelism because the computers don't share memory!
- when you use 1 computer, you just hope it doesn't fail. If it does, you go to the store, buy a new one and restart the job.
- when you use 1000s of computers at a time, failures become the norm. what to do when 1 of 1000 computers fail. Start over?

## Big Jobs ---> Better Abstractions

Need high-level interfaces to shield application programmers from the complex details. Complex implementations solve the problems of distribution, fault tolerance and performance.

Common abstraction: Parallel collections

Example collections: sets, tables, dictionaries, sequences Example bulk operations: create, map, reduce, join, filter

## PARALLEL SEQUENCES

## Parallel Sequences

- Parallel sequences

$$
<\mathrm{e} 1, \mathrm{e} 2, \mathrm{e} 3, \ldots, \mathrm{en}>
$$

- Operations:
- creation (called tabulate)
- indexing an element in constant span
- map
- scan -- like a fold: <u, u + e1, u +e1 +e2, ...> log n span!
- Languages:
- Nesl [Blelloch]
- Data-parallel Haskell

## Parallel Sequences: Selected Operations

```
tabulate : (int -> 'a) -> int -> 'a seq
tabulate f n == <f 0, f 1, ..., f (n-1)>
work = O(n) span = O(1)
```

## Parallel Sequences: Selected Operations

```
tabulate : (int -> 'a) -> int -> 'a seq
tabulate f n == <f 0, f 1, ..., f (n-1)>
work = O(n) span = O(1)
```

nth : 'a seq -> int -> 'a
nth <e0, e1, ..., e(n-1)> i == ei
work $=O(1) \quad$ span $=O(1)$

## Parallel Sequences: Selected Operations

```
tabulate : (int -> 'a) -> int -> 'a seq
tabulate f n == <f 0, f 1, ..., f (n-1)>
work = O(n) span = O(1)
```

```
nth : 'a seq -> int -> 'a
nth <e0, e1, ..., e(n-1)> i == ei
work = O(1) span = O(1)
```

length : 'a seq -> int
length $<e 0, e 1, \ldots, e(n-1)>==n$
work $=O(1) \quad \operatorname{span}=O(1)$

## Problems

(1) Write a function that creates the sequence $<0, \ldots, n-1>$ with Span $=O(1)$ and Work $=O(n)$.
(2) Write a function such that given a sequence <v0, ..., vn-1>, maps fover each element of the sequence with Span $=0(1)$ and Work $=O(n)$, returning the new sequence (if f is constant work)
(3) Write a function such that given a sequence <v1, ..., vn-1>, reverses the sequence. with $\operatorname{Span}=O(1)$ and Work $=O(n)$

Operations:
Try it!

|  |  | Work | Span |
| :--- | :--- | :--- | :--- |
| tabulate f n | n | 1 |  |
| nth i s |  | 1 | 1 |
| length s |  | 1 | 1 |

## Solutions

(* create $n=<0,1, \ldots, n-1\rangle *$ )
let create $\mathrm{n}=$
(* map $f<v 0, \ldots, v n-1\rangle==\langle f v 0, \ldots, f v n-1\rangle *$ )
let $\operatorname{map} \mathrm{f} \mathrm{s}=$
(* reverse <vo, ..., vn-1> == <vn-1, ..., vo> *)
let reverse $s=$

## Solutions

(* create $n=<0,1, \ldots, n-1\rangle *$ )
let create $\mathrm{n}=$ tabulate (fun i $->$ i) $n$
(* map $f<v 0, \ldots, v n-1\rangle==\langle f v 0, \ldots, f v n-1\rangle *$ )
let $\operatorname{map} \mathrm{f}=$
(* reverse <vo, ..., vn-1> == <vn-1, ..., vo> *)
let reverse $s=$

## Solutions

(* create $n=<0,1, \ldots, n-1\rangle *$ )
let create $\mathrm{n}=$
tabulate (fun i -> i) n
(* map $f<v 0, \ldots, \operatorname{vn}-1\rangle==\langle f v 0, \ldots, f v n-1\rangle *$ )
let map $f$ s =
tabulate (fun i $->$ nth $s$ i) (length $s$ )
(* reverse <vo, ..., vn-1> == <vn-1, ..., vo> *)
let reverse $s=$

## Solutions

(* create $n=<0,1, \ldots, n-1\rangle *$ )
let create $\mathrm{n}=$
tabulate (fun i -> i) n
(* map $f<v 0, \ldots, v n-1>==\langle f v 0, \ldots, f v n-1>*$ )
let map f $\mathrm{s}=$ tabulate (fun i $->$ nth $s$ i) (length $s$ )
(* reverse <vo, ..., vn-1> == <vn-1, ..., vo> *)
let reverse $s=$
let $\mathrm{n}=$ length s in
tabulate (fun $i \rightarrow n$ nh $s(n-i-1)) n$

## One more problem

- Consider the problem of determining whether a sequence of parentheses is balanced or not. For example:
- balanced: ()()(())
- not balanced: ( or ) or ()))
- Try formulating a divide-and-conquer parallel algorithm to solve this problem efficiently:

```
type paren = L | R (* L(eft) or R(ight) paren *)
let balanced (ps : paren list) : bool = ...
```

- You will need another function on sequences:

```
(* split s n divides s in to (s1, s2) such that s1 is
    the first n elements of s and s2 is the rest
    Work = O(n) Span = O(1) *)
split : 'a sequence -> int -> 'a sequence * 'a sequence
```

## A Parallel Sequence API

```
type 'a seq
tabulate : (int -> 'a) -> int -> 'a seq
length : 'a seq -> int
nth : 'a seq -> int -> 'a
```

append : 'a seq -> 'a seq -> 'a seq

```
append : 'a seq -> 'a seq -> 'a seq
split : 'a seq -> int -> 'a seq * 'a seq O(N)
```

split : 'a seq -> int -> 'a seq * 'a seq O(N)

```
```

O(N+M)

For efficient implementations, see Blelloch's NESL project: http://www.cs.cmu.edu/~scandal/nesl.html

## Fold and Reduce

We have seen many sequential algorithms can be programmed succinctly using fold or reduce. Eg: sum all elements:
sum:

## Fold and Reduce

We have seen many sequential algorithms can be programmed succinctly using fold or reduce. Eg: sum all elements:

## Fold and Reduce

We have seen many sequential algorithms can be programmed succinctly using fold or reduce. Eg: sum all elements:

## Fold and Reduce

We have seen many sequential algorithms can be programmed succinctly using fold or reduce. Eg: sum all elements:

let sum_all (l:int list) = reduce (+) 0 l

## Fold and Reduce

We have seen many sequential algorithms can be programmed succinctly using fold or reduce. Eg: sum all elements:

```
let sum_all (l:int list) = reduce (+) 0 l
```

Key to parallelization: Notice that because sum is an associative operator, we do not have to add the elements strictly left-to-right:

$$
((((\text { init }+v 1)+v 2)+v 3)+v 4)+v 5)==((\text { init }+v 1)+v 2)+((v 3+v 4)+v 6)
$$

## Side Note

The key is associativity:
$(((($ init $+v 1)+v 2)+v 3)+v 4)+v 5)=(($ init $+v 1)+v 2)+((v 3+v 4)+v 6)$
add on processor 1 add on processor 2

Commutativity allows us to reorder the elements:

$$
\mathrm{v} 1+\mathrm{v} 2==\mathrm{v} 2+\mathrm{v} 1
$$

But we don't have to reorder elements to obtain a significant speedup; we just have to reorder the execution of the operations.

## Parallel Sum

| 2 | 7 | 4 | 3 | 9 | 8 | 2 | 1 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

## Parallel Sum

## Parallel Sum

## Parallel Sum

## Parallel Sum

## Parallel Sum

## Splitting Sequences

```
type 'a treeview =
    Empty
    | One of 'a
    | Pair of 'a seq * 'a seq
let show tree (s:'a seq) : 'a treeview =
    match length s with
        0 -> Empty
    | 1 -> One (nth s 0)
    | n -> Pair (split s (n/2))
```

## Parallel Sum

```
let rec psum (s : int seq) : int =
    match treeview s with
        Empty -> 0
    | One v -> v
    | Pair (s1, s2) ->
        let (n1, n2) = both psum s1
        psum s2 in
        n1 + n2
```

## Parallel Reduce

If op is associative and the base case has the properties:

$$
\text { op base } X==X \quad \text { op } X \text { base }==X
$$

then the parallel reduce is equivalent to the sequential left-to-right fold.

## Parallel Reduce

let rec reduce (f:'a -> 'a -> 'a) (base:'a) (s:'a seq) = match treeview s with

Empty -> base
| One v -> f base v
| Pair (si, sh) ->
let $(\mathrm{n} 1, \mathrm{n} 2)=$ both reduce s 1 reduce se in
f nl n2

## Parallel Reduce

let rec reduce (f:'a -> 'a -> 'a) (base:'a) (s:'a seq) = match treeview s with

Empty -> base
| One v -> f base v
| Pair (si, sh) ->
let $(\mathrm{n} 1, \mathrm{n} 2)=$ both reduce s 1 reduce s2 in
f nl n2
let sum $s=$ reduce $(+) 0$ s

## A little more general

```
let rec mapreduce (inject: 'a -> 'b)
    (combine:'b -> 'b -> 'b)
    (base:'b)
    (s:'a seq) =
```

match treeview s with
Empty -> base
| One v -> inject v
| Pair (s1, s2) ->
let $(r 1, r 2)=$ both mapreduce s1
mapreduce s2 in
combine r1 r2

## A little more general

let rec mapreduce (inject: 'a $->$ 'b)
(combine:'b -> 'b -> 'b)
(base:'b)
(s:'a seq) =
match treeview s with
Empty -> base
| One v -> inject v
| Pair (s1, s2) ->
$\begin{aligned} \text { let }(r 1, r 2)=\text { both } & \text { mapreduce } s 1 \\ & \text { mapreduce } s 2 \text { in }\end{aligned}$
combine r1 r2
let count $s=$ mapreduce (fun $x->1)(+) 0 \mathrm{~s}$

## A little more general

let rec mapreduce (inject: 'a $->$ 'b)
(combine:'b -> 'b -> 'b)
(base:'b)
(s:'a seq) =
match treeview s with
Empty -> base
| One v -> inject v
| Pair (si, sh) ->
let $(r 1, r 2)=$ both mapreduce si
mapreduce $s 2$ in
combine ri ra
let count $s=$ mapreduce (fun $x->1)(+) 0 \mathrm{~s}$
let average $s=$
let (count, total) =
mapreduce (fun $x->(1, x)$ )
(fun (c1,t1) (c2,t2) -> (c1+c2, ti + th))
$(0,0) \mathrm{s}$ in
if count $=0$ then 0 else total / count

## Parallel Reduce with Sequential Cut-off

When data is small, the overhead of parallelization isn't worth it. You should revert to the sequential version.

```
type 'a treeview =
    Small of 'a seq | Big of 'a treeview * 'a treeview
let show_tree (s:'a seq) : 'a treeview =
    if length s < sequential_cutoff then
        Small s
    else
        Big (split s (n/2))
```

let rec reduce $f$ base $s=$
match treeview s with
Small s -> sequential_reduce f base s
| Big (si, si) ->
let (ni, n2) = both reduce si
reduce s2 in
f ni ne

## BALANCED PARENTHESES

## The Balanced Parentheses Problem

Consider the problem of determining whether a sequence of parentheses is balanced or not. For example:

- balanced: ()()())
- not balanced: (
- not balanced: )
- not balanced: ()))

We will try formulating a divide-and-conquer parallel algorithm to solve this problem efficiently:

```
type paren = L | R (* L(eft) or R(ight) paren *)
let balanced (ps : paren seq) : bool = ...
```

## First, a sequential approach

fold from left to right, keep track of \# of unmatched right parens

## First, a sequential approach

fold from left to right, keep track of \# of unmatched right parens

| 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

$0 \quad 1$

## First, a sequential approach

fold from left to right, keep track of \# of unmatched right parens

## First, a sequential approach

fold from left to right, keep track of \# of unmatched right parens

## First, a sequential approach

fold from left to right, keep track of \# of unmatched right parens

## First, a sequential approach

fold from left to right, keep track of \# of unmatched right parens

too many right parens indicates no match

## First, a sequential approach

if you reach the end of the end of the sequence, you should have no unmatched left parens

## Easily Coded Using a Fold

```
let rec fold f b s =
    let rec aux n accum =
        if n >= length s then
            accum
        else
            aux (n+1) (f (nth s n) accum)
    in
    aux 0 b
```

## Easily Coded Using a Fold

(* check to see if we have too many unmatched $R$ parens
so_far : number of unmatched parens so far or None if we have seen too many $R$ parens
*)
let check (p:paren) (so_far:int option) : int option = match (p, so_far) with
(_, None) -> None
(L, Some c) -> Some (c+1)
(R, Some 0) -> None (* violation detected *)
( R , Some c) -> Some ( $\mathrm{c}-1$ )

## Easily Coded Using a Fold

let fold f base s = ...
let check so_far s = ...
let balanced (s: paren seq) : bool = match fold check (Some O) s with Some 0 -> true
| (None | Some n) -> false

## Parallel Version

- key insights
- if you find () in a sequence, you can delete it without changing the balance

## Parallel Matcher

(* delete all () and return the (j, k) corresponding to:
)) ) ... j ... ) ) ) ((( . . . k ... (( (
*)
let rec matcher $s=$ match show tree $s$ with Empty -> (0, 0)
| One L -> (0, 1)
| One R -> (1, 0)
| Pair (left, right) ->
let $(j, k),(x, y)=$ both matcher left matcher right in
if $x>k$ then
$(j+(x-k), y)$
else
(j, (kex) $+y$ )

## Parallel Matcher

(* delete all () and return the (j, k) corresponding to:
)) ) ... j ... ) ) ) ((( ... k ... (( (
*)
let rec matcher $s=$ match show_tree s with Empty -> (0, 0)
| One L -> (0, 1)
| One R -> (1, 0)
| Pair (left, right) ->
let $(j, k),(x, y)=b o t h$ matcher left matcher right
if $x>k$ then
$(j+(x-k), y)$
else
(j, (kex) $+y$ )

## Parallel Balance

(* *)
let matcher $s=$...
(* true if $s$ is a sequence of balanced parens *)
let balanced $s=$
match matcher $s$ with
$\mid(0,0)->$ true
(i,j) $->$ false
Work: O(N)
Span: O(log N)

## Using a Parallel Fold

let rec mapreduce(inject: 'a -> 'b)
let inject pare = match paren with

$$
\begin{aligned}
& \quad L \quad \rightarrow(0,1) \\
& \mid \\
& \text { R } \rightarrow(1,0)
\end{aligned}
$$

let combine (j,k) (x,y) =

$$
\begin{array}{ll}
\text { if } x>k \text { then }(j+(x-k), y) \\
\text { else } & (j,(k-x)+y)
\end{array}
$$

let balanced s = match mapreduce inject combine $(0,0)$ s with | ( 0,0 ) -> true
| (i,j) -> false

## Using a Parallel Fold

let rec mapreduce(inject: 'a -> 'b) (combine:'b $->\quad$ 'b $b>\quad$ 'b) (base:'b)
(s:'a seq) = ...
let inject paren = match paren with

L $->(0,1)$
$\mid R->(1,0)$
For correctness, check the associativity of combine
also check:

## combine base $(\mathrm{i}, \mathrm{j})==(\mathrm{i}, \mathrm{j})$

let combine $(j, k)(x, y)=$

$$
\begin{array}{ll}
\text { if } x>k \text { then } & (j+(x-k), y) \\
\text { else } & (j,(k-x)+y)
\end{array}
$$

let balanced $s=$ match mapreduce inject combine $(0,0)$ s with | ( 0,0 ) $->$ true
| (i,j) -> false

## Hey, wait a minute...

- key insights
- if you find () in a sequence, you can delete it without changing the balance
- if you have d

Dang! All that stuff about deleting parens seems complicated.
I liked the other way better, scanning from left to right, incrementing/ decrementing the count.

- for divide-ar
- combining
$-1)) \ldots j \ldots))(((\ldots \quad 0 \quad 1 \quad 2 \quad 1 \quad 0 \quad-1!!$
- if $x>k$ then ))) ... j ... ))) ))) ... $x-k$... ))) ((( ... y ... (((
- if $x<k$ then ))) ... j ... ))) ((( ... k-x ... ((( (( ... y ... (()

## A nicer solution

let rec mapreduce (inject: 'a -> 'b) (combine:'b -> 'b -> 'b)
(base:'b)
(s:'a seq) = ...

let check (p:paren) (so_far:int option) : int option = match (p, so_far) with
(_, None) -> None
| (L, Some c) -> Some (c+1)
| (R, Some 0) -> None
| (R, Some C) -> Some (c-1)

## A nicer solution

let rec mapreduce (inject: 'a -> 'b) (combine:'b -> 'b -> 'b) (base:'b) (s:'a seq) = ...
type $t=i n t$ option $->$ int option
let inject: paren $->t=$ (*you fill in the blanks!*)

let base: $t=\quad(*$ you fill in the blanks!*)
let finish: $t \rightarrow$ bool $=$ (* you fill in the blanks!*)
let balanced (s: paren seq) = finish (mapreduce inject combine base)

## A nicer solution

```
let rec mapreduce(inject: 'a -> 'b)
    (combine:'b -> 'b -> 'b)
    (base:'b)
    (s:'a seq) = ...
type t = int option -> int option
let inject: paren -> t = check
let combine: t -> t -> t = funfgx }->\textrm{f}(\textrm{gx})\quad(*\mathrm{ compose*)
let base: t = fun }x->
let finish: t -> bool =
        fun f }->\mathrm{ match (f (Some 0)) with Some 0 true | _ false
let balanced (s: paren seq) =
    finish (mapreduce inject combine base)
```

## A nicer solution

```
let ren maned, si, 'a -> 'b)
        check the associativity
                of combine -
                        super easy! also check: combine base \(\mathrm{x}=\mathrm{x}\) super easy!
type t = int option -> int option
let inject: paren -> t = check
let combine: t -> t -> t = funfgx f f(gx) (* compose*)
let base: t = fun }x->
let finish: t -> bool =
    fun f }->\mathrm{ match (f (Some 0)) with Some 0 }->\mathrm{ true |_ }->\mathrm{ false
let balanced (s: paren seq) =
    finish (mapreduce inject combine base)
```

## The "nicer solution" is beautiful but useless

mapreduce computes, efficiently, in parallel, a big function composition; then the "finish" function runs that function, which is when all the computation takes place, SEQUENTIALLY!

## Double Dang!

type $t=i n t$ option -> int option
let inject: paren -> $t=$ check
let combine: t -> t -> $\mathrm{t}=\mathrm{funfgx} \mathrm{f}(\mathrm{gx}) \quad$ (* compose *)
let base: $t=\quad$ fun $x \rightarrow x$
let finish: t -> bool =
fun $\mathrm{f} \rightarrow$ match ( f (Some 0) ) with Some $0 \rightarrow$ true $\left.\right|_{-} \rightarrow$ false
let balanced (s: paren seq) = finish (mapreduce inject combine base)

## Exercise

Let $s$ be a sequence of "digits" :

$$
s=\begin{array}{|l|l|l|l|l|l|l|l|}
\hline 3 & 1 & 4 & 1 & 5 & 9 & 2 & 6 \\
\hline
\end{array}
$$

Compute the decimal value of $s$ :
inject: int -> int $=$ fun $d->d$
combine ( $v$ : int) ( $d$ : int) $=v^{*} 10+d$
base $=0$
combine (combine (combine (combine 0 3) 1) 4) 1 == 3141

Now, compute really fast in parallel: mapreduce inject combine base $s==31415926$, right?

## Exercise

Let $s$ be a sequence of "digits" :

$$
\mathrm{s}=\begin{array}{|l|l|l|l|l|l|l|l|}
\hline 3 & 1 & 4 & 1 & 5 & 9 & 2 & 6 \\
\hline
\end{array}
$$

Compute the decimal value of $s$ :
inject: int -> int $=$ fun $d->d$
combine ( $v$ : int) ( $d$ : int) $=v^{*} 10+d$ base $=0$

combine (combine (combine (combine 03) 1) 4) $1=3141$

Now, compute really fast in parallel: mapreduce inject combine base $s==31415926$, right?

## Another Exercise

$\sum_{i=0}^{n-1} f(i)$

$$
f: \text { int } \rightarrow \text { float }
$$

inject: int -> float $=\mathrm{f}$
combine ( $x$ : float) $(y$ : float) $=x+. y$
 base $=0$.

Now, compute really fast in parallel: mapreduce inject combine base s

## Floating-point addition is not associative!

Consider 6-digit mantissas:

| $.100000 \times 10^{0}$ | $.400000 \times 10^{-6}$ |
| :--- | :--- |
| $.0000004 \times 10^{0}$ | $.400000 \times 10^{-6}$ |
| $.000000 \times 10^{0}$ | $.800000 \times 10^{-6}$ |

$((.100000+.0000004)+.0000004)+.0000004=.100000$
$.100000+(.0000004+(.0000004+.0000004))=.100001$

For some summations, this matters a lot!
In other cases, it doesn't matter.
So we can't tell whether there's a bug in the program.

## PARALLEL SCAN AND PREFIX SUM

## The prefix-sum problem

Sum of Sequence:

input | 6 | 4 | 16 | 10 | 16 | 14 | 2 | 8 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

output 76

Prefix-Sum of Sequence:

input | 6 | 4 | 16 | 10 | 16 | 14 | 2 | 8 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

output | 6 | 10 | 26 | 36 | 52 | 66 | 68 | 76 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

## The prefix-sum problem

## val prefix_sum : int seq -> int seq

input | 6 | 4 | 16 | 10 | 16 | 14 | 2 | 8 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

output | 6 | 10 | 26 | 36 | 52 | 66 | 68 | 76 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

The simple sequential algorithm: accumulate the sum from left to right

- Sequential algorithm: Work: $O(n)$, Span: $O(n)$
- Goal: a parallel algorithm with Work: O(n), Span: O(log n)

## Parallel prefix-sum

The trick: Use two passes

- Each pass has $O(n)$ work and $O(\log n)$ span
- So in total there is $O(n)$ work and $O(\log n)$ span

First pass builds a tree of sums bottom-up

- the "up" pass

Second pass traverses the tree top-down to compute prefixes

- the "down" pass computes the "from-left-of-me" sum

Historical note:

- Original algorithm due to R. Ladner and M. Fischer, 1977

## Example

input

| 6 | 4 | 16 | 10 | 16 | 14 | 2 | 8 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

output $\square$

## Example

input

| 6 | 4 | 16 | 10 | 16 | 14 | 2 | 8 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 6 | 10 | 26 | 36 | 52 | 66 | 68 | 76 |

## The algorithm, pass 1

1. Up: Build a binary tree where

- Root has sum of the range $[\mathbf{x}, \mathbf{y})$
- If a node has sum of [lo,hi) and hi>lo,
- Left child has sum of [lo, middle)
- Right child has sum of [middle, hi)
- A leaf has sum of [i,i+1), i.e., nth input i

This is an easy parallel divide-and-conquer algorithm: "combine" results by actually building a binary tree with all the range-sums

- Tree built bottom-up in parallel

Analysis: $O(n)$ work, $O(\log n)$ span

## The algorithm, pass 2

2. Down: Pass down a value fromLeft

- Root given a fromLeft of 0
- Node takes its fromLeft value and
- Passes its left child the same fromLeft
- Passes its right child its fromLeft plus its left child's sum
- as stored in part 1
- At the leaf for sequence position $i$,
- nth output i $==$ fromLeft + nth input $i$

This is an easy parallel divide-and-conquer algorithm: traverse the tree built in step 1 and produce no result

- Leaves create output
- Invariant: fromLeft is sum of elements left of the node's range

Analysis: $O(n)$ work, $O(\log n)$ span

## Sequential cut-off

For performance, we need a sequential cut-off:

- Up:
- just a sum, have leaf node hold the sum of a range
- Down:
- do a sequential scan

## Parallel prefix, generalized

Just as map and reduce are the simplest examples of a common pattern, prefix-sum illustrates a pattern that arises in many, many problems

- Minimum, maximum of all elements to the left of $i$
- Is there an element to the left of $i$ satisfying some property?
- Count of elements to the left of $i$ satisfying some property
- This last one is perfect for an efficient parallel filter ...
- Perfect for building on top of the "parallel prefix trick"

## Parallel Scan

scan (o) <x1, ..., xn>
=
<x1, x1 o x2, ..., x1 o ... o xn>
like a fold, except return the folded prefix at each step
pre_scan (o) base <x1, ..., xn>
=
<base, base o x1, ..., base o x1 o ... o xn-1>

sequence with o applied to all items to the left of index in input

## Parallel Filter

Given a sequence input, produce a sequence output containing only elements $v$ such that ( $£ \mathrm{v}$ ) is true

Example: let $\mathrm{f} x=\mathrm{x}>10$

$$
\begin{aligned}
& f i l t e r f<17,4,6,8,11,5,13,19,0,24> \\
= & <17,11,13,19,24\rangle
\end{aligned}
$$

Parallelizable?

- Finding elements for the output is easy
- But getting them in the right place seems hard

## Parallel prefix to the rescue

Use parallel map to compute a bit-vector for true elements:

$$
\begin{aligned}
& \text { input }<17,4,6,8,11,5,13,19,0,24\rangle \\
& \text { bits }<1,0,0,0,1,0,1,1,0,1\rangle
\end{aligned}
$$

Use parallel-prefix sum on the bit-vector:

$$
\text { bitsum }<1,1,1,1,2,2,3,4,4,5>
$$

For each $i$, if bits[ $[i]==1$ then write input $[i]$ to output[bitsum[i]] to produce the final result:
output <17, 11, 13, 19, 24>

## QUICKSORT

## Quicksort review

## Recall quicksort was sequential, in-place, expected time $O(n \log n)$

1. Pick a pivot element Best / expected case work
2. Partition all the data into: O(1)
A. The elements less than the pivot
B. The pivot
C. The elements greater than the pivot
3. Recursively sort A and C
$2 \mathrm{~T}(\mathrm{n} / 2)$

How should we parallelize this?

## Quicksort

Best / expected case work

1. Pick a pivot element O(1)
2. Partition all the data into:

O(n)
A. The elements less than the pivot
B. The pivot
C. The elements greater than the pivot
3. Recursively sort A and C
$2 \mathrm{~T}(\mathrm{n} / 2)$

Easy: Do the two recursive calls in parallel

- Work: unchanged. Total: $O(n \log n)$
- Span: now $T(n)=O(n)+1 T(n / 2)=O(n)$

## Doing better

As with mergesort, we get a $O(\log n)$ speed-up with an infinite number of processors. That is a bit underwhelming

- Sort $10^{9}$ elements 30 times faster
(Some) Google searches suggest quicksort cannot do better because the partition cannot be parallelized
- The Internet has been known to be wrong $)$
- But we need auxiliary storage (no longer in place)
- In practice, constant factors may make it not worth it

Already have everything we need to parallelize the partition...

## Parallel partition (not in place)

Partition all the data into:
A. The elements less than the pivot
B. The pivot
C. The elements greater than the pivot

This is just two filters!

- We know a parallel filter is $O(n)$ work, $O(\log n)$ span
- Parallel filter elements less than pivot into left side of aux array
- Parallel filter elements greater than pivot into right size of aux array
- Put pivot between them and recursively sort

With $O(\log n)$ span for partition, the total best-case and expectedcase span for quicksort is

$$
\mathrm{T}(n)=O(\log n)+1 \mathrm{~T}(n / 2)=O\left(\log ^{2} n\right)
$$

## Example

Step 1: pick pivot as median of three

| 8 | 1 | 4 | 9 | 0 | 3 | 5 | 2 | 7 | 6 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

Steps 2a and 2c (combinable): filter less than, then filter greater than into a second array

Step 3: Two recursive sorts in parallel

- Can copy back into original array (like in mergesort)

## More Algorithms

- To add multiprecision numbers.
- To evaluate polynomials
- To solve recurrences.
- To implement radix sort
- To delete marked elements from an array
- To dynamically allocate processors
- To perform lexical analysis. For example, to parse a program into tokens.
- To search for regular expressions. For example, to implement the UNIX grep program.
- To implement some tree operations. For example, to find the depth of every vertex in a tree
- To label components in two dimensional images.

See Guy Blelloch "Prefix Sums and Their Applications"

## Summary

- Parallel prefix sums and scans have many applications
- A good algorithm to have in your toolkit!
- Key idea: An algorithm in 2 passes:
- Pass 1: build a "reduce tree" from the bottom up
- Pass 2: compute the prefix top-down, looking at the leftsubchild to help you compute the prefix for the right subchild

## PARALLEL COLLECTIONS IN THE "REAL WORLD"

## Big Data

If Google wants to index all the web pages (or images or gmails or google docs or ...) in the world, they have a lot of work to do

- Same with Facebook for all the facebook pages/entries
- Same with Twitter
- Same with Amazon
- Same with ...

Many of these tasks come down to map, filter, fold, reduce, scan

## FScala

Parallel Collections with Scala

The Bloom Programming Language

LINQ

## Google Map-Reduce

Google MapReduce (2004): a fault tolerant, massively parallel functional programming paradigm

- based on our friends "map" and "reduce"
- Hadoop is the open-source variant
- Database people complain that they have been doing it for a while
- ... but it was hard to define

Fun stats circa 2012:

- Big clusters are $\sim 4000$ nodes
- Facebook had 100 PB in Hadoop
- TritonSort (UCSD) sorts 900GB/minute on a 52-node, 800-disk hadoop cluster

## Data Model \& Operations

- Map-reduce operates over collections of key-value pairs
- millions of files (eg: web pages) drawn from the file system
- The map-reduce engine is parameterized by 3 functions:

## Architecture

## Iterative Jobs are Common

## A Modern Software Stack

## Workload Manager

High-level scripting language

## The Control Plane

## Flow of Information

## Jobs, Tasks and Attempts

- A single job is split in to many tasks
- Each task may include many calls to map and reduce
- Workers are long-running processes that are assigned many tasks
- Multiple workers may attempt the same task
- each invocation of the same task is called an attempt
- the first worker to finish "wins"
- Why have multiple machines attempt the same task?
- machines will fail
- approximately speaking: 5\% of high-end disks fail/year
- if you have 1000 machines: 1 failure per week
- repeated failures become the common case
- machines can partially fail or be slow for some reason
- reducers can't start until all mappers complete

## Sort-of Functional Programming in Java

## Hadoop interfaces:

```
interface Mapper<K1,V1,K2,V2> {
    public void map (K1 key,
    V1 value,
    OutputCollector<K2,V2> output)
```

interface Reducer<K2,V2,K3,V3> \{
public void reduce (K2 key,
Iterator<V2> values,
OutputCollector<K3,V3> output)
\}

## Word Count in Java

```
class WordCountMap implements Map {
    public void map(DocID key
                                List<String> values,
                                OutputCollector<String,Integer> output)
    {
        for (String s : values)
        output.collect(s,1);
    }
}
```

class WordCountReduce \{
public void reduce(String key,
Iterator<Integer> values,
OutputCollector<String,Integer> output)
\{
int count $=0$;
for (int $v$ : values)
count += 1;
output.collect(key, count)
\}

## Summary

Folds and reduces are easily coded as parallel divide-andconquer algorithms with $\mathrm{O}(\mathrm{N})$ work and $\mathrm{O}(\log n)$ span

Scans are trickier and use a 2-pass algorithm that builds a tree.

The map-reduce-fold paradigm, inspired by functional programming, is a big winner when it comes to big data processing.

Hadoop is an industry standard but higher-level data processing languages have been built on top.
